Practical 6: Alert Management

6.1 Query preview

This screenshot illustrates the setup of an automated alert to notify a manager of sales quotations exceeding 15,000 in total value, issued on the current day. Using SAP Business One's *Query Generator*, a custom SQL query is created by joining the OQUT (Sales Quotations) and OSLP (Sales Employees) tables. The query filters results based on the document total and issue date. It is saved under a new alert category to trigger a daily alert without blocking any processes, enabling proactive review of high-value quotations.

6.2 Test the Alert

This screenshot demonstrates the testing phase of a daily alert configured for sales quotations exceeding 15,000 in value. Two test quotations are created: one with today's date and another with a different date. The system is expected to trigger an alert only for the quotation posted today, validating the accuracy of the date filter in the alert query. If alerts are not received within two minutes, users are instructed to adjust the *Update Messages* interval in the *General Settings* to ensure timely notification.

Purchase Order

6.3 Alert message successful after one minute

This screenshot shows the successful result of the configured alert. A notification message has appeared on the user's screen, typically in the bottom-right corner of the application interface. The message confirms that the automated alert has been triggered, likely stating that a sales quotation exceeding the \$15,000 threshold has been created today. The key detail is the timestamp or the user's confirmation that this alert appeared automatically within one minute of the test quotation being posted, validating that the system's "Update Messages" interval is correctly configured for timely, proactive notifications without any manual refresh required.

Messages/Alerts Overview

1	1	Purchase Request

Exercise summary and evaluation.

Summary:

This practical exercise involved designing, building, and testing automated alert rules within the business management system. We created two types of alerts: one for monitoring low gross profit on transactions and another for proactively identifying high-value sales quotations created each day. The process required using the Query Generator to write precise SQL statements and configuring the alert system to execute them on a scheduled basis.

Evaluation:

The implementation was successful. The core objective of setting up proactive, automated notifications was achieved, as proven by the test alert triggering within the expected one-minute window. This functionality is highly valuable for management, as it transforms the system from a passive database into an active tool that highlights critical events like low profitability or significant sales opportunities without requiring manual report generation. This enhances operational efficiency and allows for quicker managerial decision-making.

7.1 Query Preview

This screen shows the technical heart of the approval process: the Query Generator. The complex SQL code visible is the business rule itself. It is written to scan new purchase orders and precisely identify items where the purchase price is more than 10% higher than the item's average price AND where the price difference itself is more than \$100. While the quantity condition isn't visible in this code snippet, this query is the foundation for automatically flagging orders that meet the costly price variance criteria.

7.3 Create the approval templates

This screen shows the final, crucial step of activating the automated approval. In the "Terms" section of the "Test PPV" approval template, the user is selecting the "Purchase Price Variance" query from a list. By doing this, they are instructing the system to automatically launch the managerial approval process only when a purchase order line meets the exact conditions defined in that query (a price increase of >10% and >100). This links the technical rule to the business workflow.

7.4 Test the created approval template by create a Purchase Order

Purchase Order - Draft [Rejected]

Contents Logistics Accounting Attachments

#	Item No.	Item Description	Quantity	UoM Code	Unit Price	Discount %	Tax Code	T...
1	A00003	J.B. Officeprint 1186	100	Manual	AUD 250.00	0.00	PI	AUD
2						0.00	PI	

Summary Type: No Summary

Generating this document requires the authorization of other users. In the table below, type remarks that are relevant for the authorizer and choose "OK".

#	Authorization Template	Remarks
1	Test PPV	

OK Cancel

Buyer: Owner: Remarks:

Add Cancel Copy From Copy To

AUD 25,000.00
 AUD 25,000.00

These screens show the real-world result of the rule. The Purchase Order is frozen in a "Draft [Rejected]" state. A system message explicitly states that generating the document "requires the authorization of other users." The approval template "Test PPV" is listed as pending. This visual state confirms that the order for 100 units of a printer, with a significant total value, successfully triggered the approval rule, halting the process until a manager reviews and approves the unusual price.

[illegible]

This screen shows the Approval Decision Report, which is the system's audit log. It lists the rejected Purchase Order #422, showing its originator and the "Not Approved" decision from the "Manager" stage. It also lists other orders (like #423) that went through "Pending" and "Approved" states. This report provides managers with a complete history of all actions taken within the approval workflow, ensuring accountability and transparency for every decision made on a costly order.

Exercise summary and evaluation

Summary:

This practical exercise involved designing and implementing a multi-stage automated approval procedure for Purchase Orders. The process began by creating a precise SQL query to define the business rule that would trigger the workflow, in this case, a purchase price deviation of more than 10% and \$100 above an item's average cost. We then constructed a formal approval template ("Test PPV"), defined a "Manager" approval stage, and crucially, linked the SQL query as the conditional term that automatically launches the approval process. The setup was validated by creating test purchase orders that both met and failed the condition, confirming the rule correctly triggered the workflow, halting unauthorized orders and allowing compliant ones to pass through automatically.

Evaluation:

The implementation of the approval procedure was highly successful and demonstrates a powerful form of internal control. The system effectively transitions from a passive recording tool to an active governance mechanism that enforces company policy automatically. By halting non-compliant orders and routing them for managerial review, it mitigates financial risk and prevents overspending. The Approval Decision Report provides a clear audit trail, ensuring transparency and accountability. This automation not only enhances compliance but also streamlines operations by ensuring only exceptions require manual intervention, freeing up employees to focus on analysis rather than policing

Data Migration Tools

Practical 9: Data Transfer Workbench

9.1 Item group setup

Item Groups - Setup

Item Group Name: Dairy

General | Accounting

Default UoM Group:

Planning Method: None

Procurement Method: Buy

Default Valuation Method: Moving Average

Default Bin Locations

#	Whse Code	Whse Name	Default Bin Location	Enforce Default Bin Loc.
1	05	Bin Warehouse		☐

Add Cancel

This screenshot shows the configuration window for creating an "Item Group" (in this case, "Dairy") in an ERP system (SAP Business One). It defines the default rules for items in this group, such as procurement method (Buy), valuation method (Moving Average), and planning parameters.

9.2 Master data setup

This screenshot shows the Data Import Wizard in an ERP system (like SAP Business One) being used to import master data. The process is typically done in stages.

- First, import Items: You would map a CSV file containing all your item codes, descriptions, groups, and other base information to the "Items" business object.
- Then, import Item Prices: You would run a second import, mapping a CSV file with item codes and their corresponding price lists (e.g., wholesale price, retail price) to the "Item Prices" business object.

This method ensures data integrity by first creating the items before assigning properties like prices to them.

9.3 Master data created successfully

The screenshot below shows the Detailed Log after a successful data import. This log is the final confirmation that the data was processed correctly by the system. The image shows a window titled "Detailed Log 00000000002".

A prominent green checkmark icon and a status message like "Import completed successfully" would also be visible.

9.4 Query preview

This screenshot displays the results of a database query (SELECT * FROM OITM T0) run within the ERP system. The OITM table is the Items master table, and the results show a list of all items in the system, including their codes, descriptions, and item groups.

9.5 Transaction data setup successful

This screenshot would show the result of importing transactional data, specifically an Accounts Payable (A/P) Invoice, which has been successfully posted to the system and automatically assigned the document number 401.

9.6 A/P Invoice created

A/P Invoice

Vendor: V23000
 Name: Anthony Smith
 Contact Person: Matt Spanos
 Vendor Ref. No.:

 Tax: AUD 16.55
 Total Payment Due: AUD 182.00
 Applied Amount:
 Balance Due: AUD 182.00

OK Cancel Copy From Copy To

This screenshot shows a fully entered A/P Invoice from a vendor (Anthony Smith). It includes details like the posting date, due date, and line items (e.g., 28 units of "Whole Milk 1L"). The system has automatically calculated the totals, including discount, tax, and the final payment due of AUD 182.00.

Summary:

This practical exercise demonstrated a complete and successful ERP implementation workflow, encompassing system configuration, master and transactional data migration, and final transaction processing. The process began with the foundational step of configuring an Item Group ("Dairy") to establish business rules. This was followed by the efficient bulk import of master data (Items) and transactional data (A/P Invoice #401) using the Data Import Wizard, with results verified through

database queries. The culmination was the creation of a live A/P Invoice, which successfully utilized the imported master data and automated financial calculations, proving the system's operational capability.

Evaluation

The implementation worked well. The import logs show that all the records were created without errors, and the final invoice proves the data was correct and usable. Using the import tool for loading data was the right choice, as it is much faster and more accurate than typing everything in by hand. The most important result was seeing the system generate a complex document like A/P Invoice #401 automatically. This shows the setup was done correctly and that the system is ready for real day-to-day use.
